AUTHOR: Vladimirskiy, T. A., Doctor of Technical Sciences

TITLE: On the heat treatment of weld joints in gas pressure welding

PERIODICAL: Svarochnoye proizvodstvo, no. 1, 1963, 12 - 13

TEXT: The author discusses the results of an experimental investigation carried out by V. D. Taran, N. V. Bobritskiy and A. S. Fal'kevich, who consider that brief-lasting heat treatment of pressure-welded low-carbon steel joints has no substantial effect on the mechanical properties of the welds. An analysis of the experiments performed shows that the method of impact tests was not appropriate and insufficiently sensitive. To increase the sensitivity of tests, it is recommended to select conditions where the upper limit of cold brittleness approaches the test temperature, by increasing the depth of notches etc.. This condition has not been fulfilled in the aforementioned impact tests, as narrow specimens (4 mm) with a soft notch have been used. The selection of such specimens resulted in the reduced sensitivity of the test method and did not reveal the positive side of heat treatment after gas-pressure welding. In fact, even

short-time treatment improves the structure of welds and has a positive effect upon the ductility of the joints when steels with different carbon contents are used. There are 1 figure and 1 table.

AUTHOR: Vladimirskiy, T. A., Doctor of Technical Sciences

TITLE: On the use of brittle-failure sensitivity of weld joints

PERIODICAL: Svarochnoye proizvodstvo, no. 7, 1962, 39 - 40

TEXT: The author discusses some conclusions drawn by M. Kh. Shorshorov and V. D. Kodolov who analyzed the notch-sensitivity of steel with the use of Schnadt specimens having notches of different sharpness and hard inserts. (Ref. 1: Shorshorov, M. Kh., Kodolov, V. D.: "Changes in the properties of low-alloy and carbon steels of the perlite class during arc welding" - Svarochnoye proizvodstvo, 1957, no. 12. Ref. 2: Shorshorov, M. Kh., Kodolov, V. D.: "Notch-sensitivity of low-alloy and carbon steels in arc welding" - Svarochnoye proizvodstvo, 1961, no. 8). These authors consider that changes in toughness depending on the linear energy of the arc, are similar for Menager specimens and for Schnadt specimens with notches of any sharpness. Data are tabulated by the author of the present article, concerning welding conditions and toughness values for specimens with different notches, which show that an estimation of welding condi-

tions from impact tests of sharp-notched specimens may differ from results obtained with soft-notched samples. This is in accordance with the theory that the brittle sensitivity of steel can not be estimated on the basis of series tests with Menager specimens only; the low critical brittle temperature in the case of a soft notch is a necessary but insufficient condition for the low brittle-sensitivity of sharp-notched specimens. Toughness values of the weld-adjacent zone and critical brittle temperatures are compared. These data show that the evaluation of the weld-adjacent zone with the aid of soft-notched specimens is incomplete. Due to the labor-consuming manufacture of Schnadt specimens, the author recommends for practical use standard specimens such as type I and IV GOST 9454-60 specimens with round and triangular notches of 1 and 0.25 mm radius respectively. There are 2 tables. ✓

TITLE:

Addition materials for welding titanium alloys

SOURCE:

Akademiya nauk SSSR. Institut metallurgii im. A. A. Bay-
kova. Institut mineralogii, geokhimii i kristalloghimii
redkikh elementov. Mezhdunarodnaya komissiya po
redkim metallam. Vsesoyuznoye soveshchaniye po probleme
reniya. Moscow, 1958. Reniy; trudy soveshchaniye. Mos-
cow, Izd-vo AN SSSR, 1961, 203-208

TEXT: In this study the aim of the authors was to create a high-
grade Ti alloy with a variably modified structure in the cast state.
Such material is necessary to eliminate textural defects hindering
the full use of certain Ti alloys in welded structures. Details
are first given about the preparation of these addition ingredients
-- Ti-base alloys with different contents of Al, Nb, Mo, Re, Ce,

Card 1/3

Addition materials for ...

and B. Data on the macrostructure of cast alloy specimens are then cited. They suggest that the introduction of small amounts of B and B-Zr ($\ll 0.1\%$) decreases the grain size of the alloys. But this does not happen on the addition of Re and Ce, which instead causes marked granulation in the β -phase decay products. A table gives the mechanical properties of annealed alloys; it is noted that the introduction of B and B-Zr greatly strengthens Ti-Al-Nb alloy, as does the addition of Re to Ti-Al-Mo alloy. Turning to the question of the alloys' behavior during welding and plastic deformation, the authors adduce graphs to illustrate their experimental observations. These indicate that the addition of Re greatly enhances the plasticity of the welded seam in both types of alloy: The seam's bending angle is thereby increased by approx. threefold. Here Re is believed to stabilize the β -phase. The authors conclude from the results of their research that three kinds of Ti-base alloy can be employed as addition materials: 1) with Al 3, Nb 5, and Re 0.1%; 2) with Al 3, Mo 4, and Re 0.05-0.1%; and 3) with Al 5, Nb 5, and B 0.05%. The application of such materials will raise the quality

AUTHOR: Vladimirskiy, V.

TITLE: The Economy of the Countries of People's Democracies in 1958.
Statistical Materials.

PERIODICAL: Vestnik statistiki 1959, Nr 4, pp 50-74 (USSR)

ABSTRACT: The author states that industrial production of all countries with a socialist economy has increased 5 times between 1937 and 1958, whilst industrial production of capitalist countries has less than doubled during the same period. The socialist countries now possess about 1/3 of the World's population rendering 1/3 of the total production. They produce 50% of the entire grain yields and 43% of the cotton. By 1965 the socialist countries will account for more than 50% of the World's production. The author ascribes this progress, in part, to the successful economic cooperation between the countries of People's Democracies. After this introduction, the author analyzes economic results for 1958 for the individual socialist countries,

AUTHOR: ~~Vladimirskiy, V.I.~~ SOV/132-58-11-11/17

TITLE: To the Question of a Normal Series of Water Lifting Equipment for Experimental Pumping (K voprosu o normal'nom ryade vodorodnykh oborudovaniya dlya opytnykh otkachek)

PERIODICAL: Razvedka i okhrana nedr, 1958, Nr 11, pp 41 - 48 (USSR)

ABSTRACT: The VSEGINGEO Institute proposed a "normal series of water-lifting equipment" for the use of field parties in charge of testing the water, the filtration properties of the wells, etc. Thousands of tests have been made with any available water-lifting equipment; very often inadequate or even deficient. The author, in collaboration with V.I. Selikhovkin, elaborated this list (table 5) according to different types of wells and geological or other conditions. There are 5 tables.

AUTHOR: Vladimirskiy, V.I.

TITLE: Ground Water Levels During Year-Round Irrigation With Waste Water (Rezhim gruntovykh vod pri kruglogodovom orosenii stochnymi vodami)

PERIODICAL: Razvedka i Okhrana Nedr, 1958, ²⁴1, Nr 3, pp 37-45 (USSR)

ABSTRACT: The rise in population in many towns and industrial centers has caused the sharp deterioration of the quality of ground water and even of the underground water. The infiltration of polluted sewage water and an increased use of these waters for the irrigation of the agricultural fields has caused this deterioration. Irrigation with sewage water greatly improved the soil and increased the yields, and at the same time, reduced pollution of the rivers. However, there can also be many negative results of incorrect or badly conducted irrigation operations, such as a complete pollution of water-bearing layer by excrements, the increased mineralization and deterioration of the quality of the underground water and a rise in the ground water level causing marshes. At present, there is insufficient control of such fields by the administrative organizations. The author relates the results of observations

Card 1/3

132-58-3-6/15

Ground Water Levels During Year-Round Irrigation With Waste Water

conducted during the 1955-57 period on the fields in one of the kolkhozes of the Noginsk Rayon, in the Moscow Oblast'. Three experimental wells were bored, two in the sewage irrigated part and one in the naturally watered part of the kolkhoz. The water level was measured constantly during a period of 3 years in all wells and a graph was prepared (Figure 3). It showed, that any rise or fall in the irrigated part immediately provoked corresponding changes in the third well. At the same time, chemical observations were conducted in these wells. In the well with normal water the highest degree of mineralization occurred when the water level was at its lowest and receded when the only slightly-mineralized spring-water reached it. In the wells of the irrigated part the mineralization of the water increased with the water level. Slightly mineralized water filters through the soil, dissolves the minerals deposited there during the summer and flushes them into the wells. With this increased mineralization, the ground water is enriched by compounds of nitrate, nitrogene and nitrite, and in separate cases, ammonium was also found. The causes of such a large mineralization of ground water are as follows: an excessive irrigation by the

Card 2/3

132-58-3-6/15

Ground Water Levels During Year-Round Irrigation With Waste Water

sewage water during a long time; insufficient planning of the irrigated field which allowed the formation of cavities where an accumulation of sewage water was formed; insufficient control of the distributed waters allowing the accumulation of this water. Thus it is obvious, that in the planning of such irrigated fields, the interested organizations must work in close contact with the Ministerstvo geologii i okhrany nedr, SSSR (Ministry of Geology and Conservation of Mineral Resources). There are 4 figures and 8 Soviet references.

TITLE: Glass for Housing and Industrial Purposes (Steklo v zhilishchnom i promyshlennom stroitel'stve)

PERIODICAL: Steklo i Keramika, 1958, 15 Nr 5, pp 7-12 (USSR)

ABSTRACT: At present, Soviet industry produces annually 130 million m² of window glass, 1 million m² of reinforced glass, 1.25 million m² of ornate glass, and 2.4 million m² of polished glass. In the current year 2 new large glass factories are to be put into operation: the Saratov factory for polished glass, reinforced glass and ornate glass of great dimensions (up to 4.5 x 3.2 m) and a factory for window glass in the Far East. After the enlargement of the Ulan-Ude and Anzhero-Sudzhensk glass factories as well as after the building of a factory at Kazakhstan, the regions of Siberia, the Far East and Kazakhstan will be supplied with window glass of their own production. The demand for glass is, however, still greater than its output and will further increase with the building of apartments. The lack of window glass is partly also caused by wrong use in building, which is described in detail. Besides window glass many building materials and products made of glass are used at present:

Card 1/4

72-58-5-3/18

Glass for Housing and Industrial Purposes

1. Products of glass fiber, as heat and sound insulation materials in the form of sheets and mats; In the last years the production of blown glass fibers started and this caused a considerable drop of price.
2. Glass plastics, on the basis of synthetic resins and glass fiber, in form of yarns, mats and fabrics. Some of its physico-mechanical properties are mentioned in a table as compared to structural steel and aluminum. They are light and solid, they are neither subject to putrefaction nor to corrosion, and they are not hygroscopic. Experiments of the State Scientific Research Institute for Coal as well as of the Laboratory for Anisotropic Structures of the AS USSR showed that glass plastics of the SVAM type can be used for supporting coal mines which could save great amount of wood and metal. These materials can also be used for the production of poles for high-tension transmission lines, building constructions and others.
3. Glass pipes which have a great resistivity against the action of many acids, alkalies, organic solvents and other liquids, can successfully replace pipes of nonferrous metals and alloyed steels. In the last years they were used in the assembling of hidden electrical lines in apartments and houses

Card 2/4

Glass for Housing and Industrial Purposes

72-58.5-3/10

which saved many metal pipes. The Institute for Glass together with the Institute for Sanitary Engineering of the Academy for Building Activity and Architecture are carrying out experiments at present for using glass pipes for glass-concrete radiators in apartment houses. This would be a substitute for cast iron radiators and would save much metal.

4. Glass parcels consisting of two glass plates welded or stuck together, with hermetic and dehydrated air-interlayer which make it possible to save much wood in building windows.

5. Glass blocks produced at the Skopin glass factory (Ryazan' Council of National Economy) are 194 x 194 mm in size. They are used in house building.

6. Reinforced plane glass is produced in the Konstantinovka "Avtosteklo" factory, of the Gusev factory imeni Dzerzhinskiy.

7. Reinforced corrugated glass for roofs.

8. Patterned glass for doors and windows

9. Colored tiles of glass

10. Heat absorbing glass for window glass in the south of the country.

TITLE: On the Stability of Rotating Ferromagnetic Bodies
Suspended in a Magnetic Field (Ob ustoychivosti
vrashchayushchikhsya ferromagnitnykh tel,
podveshennykh v magnitnom pole)

PERIODICAL: Priory i tekhnika eksperimenta, 1959, Nr 2, pp 41-45
(USSR)

ABSTRACT: The forces acting on a rotating sphere suspended in a magnetic field are calculated and their dependence on the angular velocity of the sphere is discussed. These forces are then used to compute the trajectory of the centre of gravity of the sphere. It is shown that the position of the centre of gravity is unstable and additional damping forces must be introduced in the magnetic suspension if stability is to be achieved. Conditions which these forces should satisfy are given. Results of the calculations will also apply in a qualitative manner to magnetically suspended bodies of arbitrary form. These results are useful in the design of magnetic suspensions and explain the properties of such suspensions as reported in the literature. The theory has been verified using an installation including a heavy rotor 25 kg in

Card 1/2

On the Stability of Rotating Ferromagnetic Bodies Suspended in a
Magnetic Field

SOV/120-59-2-12/50

weight. It was found that the position of the body did in fact become unstable as soon as it was set in rotation. Beginning with a certain angular velocity the axis of rotation of the body becomes displaced parallel to itself (so that it keeps its direction in space) and its end describes a spiral on a horizontal plane. The rotation along the spiral is always in the same sense as the rotation of the body itself. To exclude aerodynamic effects the experiments were carried out in a vacuum. The phenomena observed are well represented by the theory now advanced.

F 62. GAS EMISSION AND METHOD OF ROOF CONTROL. Vladimirov, V. V.
[Ugol (Coal), July 1949, 6-8).

Expert opinion is often divergent; some consider that caving is the best method for providing against outbursts of firedamp, while others, influenced by experience obtained in the USSR, favour solid packing. At pressures up to 150 kg/cm² the greatest part of the gas contained in the coal is held in an absorbed state. With decreasing pressure this gas is released and may appear at the free surface of the coal. If an increase of rock pressure brings about mechanical disintegration of the coal, but not of the enclosing rock walls, then conditions are favourable to the liberation of gas by sudden outbursts. Gas emission depends on the speed of advance of the face and on the gas pressure. Since the permeability of the coal near to the face depends to a large degree on the pressure of the roof, the level of gas emission also is dependent on this pressure. When stowage is practised, the roof pressure is higher than it is with caving especially immediately after the breaking down of the immediate roof. When there is a succession of seams being

worked, usually 30-40% of the gas in the return air is derived from seams other than that being worked; sometimes the greater part comes from neighbouring seams. The extraction of coal lowers the pressure on underlying strata, which provokes a release of adsorbed gas from seams contained therein. The pressure of "free" gas then increases so that it may penetrate through the interjacent beds to the overlying strata. Stowage, of course, minimises this decrease of rock pressure to a certain extent, so that it should be beneficial in the working of several seams lying near to one another. The most effective way of reducing gas emission and securing its uniformity is to extract the seams simultaneously or in close succession. The method of roof control does not effect the emission of gas from an isolated seam.

Ed.: I. L. Fabelinskiy, Doctor of Physical and Mathematical Sciences; Eds. of Publishing House: A. L. Chernyak and V. G. Berkauz, Tech. Ed.: Yu. V. Rykina; Commission for Publishing the Collection in Memory of Grigoriya Samuilovich Landsberg: I. Ye. Tamm (Chairman), Academician; M. A. Leontovich, Academician; S. A. Razulin, Doctor of Physical and Mathematical Sciences; V. L. Fabelinskiy, Doctor of Physical and Mathematical Sciences; P. S. Landsberg-Baryshanskaya, Candidate of Physical and Mathematical Sciences; and G. P. Motulevich (Secretary), Candidate of Physical and Mathematical Sciences.		
PURPOSE: This book is intended for physicists and researchers engaged in the study of electromagnetic radiations and their role in investigating the structure and composition of materials.		
CONTENTS: The collection contains 30 articles which review investigations in spectroscopy, optics, molecular optics, semiconductor physics, nuclear physics, and other branches of physics. The introductory chapter gives a biographical profile of G. S. Landsberg, Professor and Head of the Department of Optics of the Division of Physical Technology at Moscow University, and reviews his work in Rayleigh scattering, combat gases, spectral analysis of metals, etc. No personalities are mentioned. References accompany each article.

TITLE: Degenerate SU(4)-symmetry of strong interactions ¹⁹ [This paper was given at the 14th Annual Conference on Nuclear Spectroscopy, Tbilisi, February 1964.]

SOURCE: Yadernaya fizika, v. 2, no. 6, 1965, 1087-1094

TOPIC TAGS: quantum number, particle interaction, baryon, radioactive decay

ABSTRACT: The assumption that strong interactions are degenerate with respect to one of the quantum numbers of the SU(4) group leads to a significant reduction of the number of states with different masses. The degenerate SU(4) super-multiplets are similar to the SU(3) super-multiplets. There is only one superfluous mass in the regular 15-dimensional representation in comparison to the octet, two in the 20-dimensional representation, similar to the baryon octet ($\Sigma^{1395}, \Lambda^{1560}$), and no superfluous masses in the 20-dimensional representation corresponding to the decuplet. Doubling the number of K-meson states makes it possible to obtain a phenomenological description of the violation of CP-parity in $K_2 \rightarrow 2\pi$ decays.

TITLE: Free ¹⁹neutrinos in space and the problem of CP-parity in the decay of K sup 0 sub 2 - mesons

SOURCE: Yadernaya fizika, v. 3, no. 4, 1966, 781-783

TOPIC TAGS: neutrino, K meson, radioactive decay, parity principle, meson beam, particle interaction, space radiation

ABSTRACT: When weak K^0 -mesons and neutrinos interact, K_L^0 can regenerate in a beam of K_S^0 -mesons. Such regeneration can lead to $K_S^0 \rightarrow 2$ decay, which would violate CP-parity; but it is shown that with the expected neutrino flux densities the effect is too small and cannot explain the observed intensity of the forbidden decay. Although coherent regeneration of K^0 mesons on a neutrino background should produce an apparent violation of CP parity, it appears to have no relation to the observed $K_L^0 \rightarrow 2$ decay. The author thanks L. B. Okun', I. Ya. Pomeranchuk, M. V. Terent'ev, and V. S. Kaftanov for interest in the work. Orig. art. has: 3 formulas. [JPRS]

Number of fine structure lines of Rayleigh scattering in optically anisotropic crystals. V. V. Vladimirov (*Compt. rend. Acad. Sci. U.R.S.S.*, 1941, 81, 866-867).--It is shown that the Rayleigh line of an optically anisotropic crystal consists of 24 satellites with changed frequencies, and one with the primary frequency. Under certain conditions some of the lines coincide, e.g., if an incident or scattered light wave is propagated along the optical axis, the no. of satellites is reduced, so that the Rayleigh line then has 13 components. Where the optical anisotropy is small, the satellites will group in fours.

Title : Heavy Water Power Reactor with Gas Cooling.

Orig Pub : Atom. energiya, 1956, No 1, 5-9

Abstract : Discussion of the advantages of heavy water nuclear reactors, which may turn out to be sufficiently economic for use in atomic electric stations. A reactor design is described, in which heavy water is used both as moderator and coolant. The factors affecting the thermal power of the reactor and the efficiency of the power portion, i.e., affecting in the final analysis the electric power of the atomic electric station, are considered. The authors reach the conclusion that the atomic electric station can be profitable if natural uranium is used, accompanied with deep burnup and maximum possible electric power, with a certain reduction in efficiency.

A heavy water power reactor with gas cooling is described. The use of gas in combination with heavy water moderator

makes it possible to increase the steam parameter in the secondary loop. The fuel elements are thin long wires of natural uranium, covered with a cladding of light metals, capable of withstanding a temperature of 550°. The coolant is carbon dioxide at a pressure of 40 -- 50 atmospheres; the coolant temperature at the input is 90°, and the output temperature is 420°. The steam pressure at the turbines is 29 atmos, and the temperature is 400°. With the aid of such a reactor one can obtain in general steam with pressures of 90 atmospheres and a temperature of 470°. It is planned in the Soviet Union to construct an atomic electric station of this type having an electric power rating of 100 -- 200 mw.

The maximum energy selected is certainly sufficient for the multiple production of mesons and for the production of the antiparticles of all known types of elementary particles. With a particle energy of from 50 to 60 BeV the kinetic energy in the center of mass system attains 9 nucleon masses on the occasion of the collision of a proton with a single nucleon. The peak power used for feeding the magnet is about 100 megawatts. The weight of the magnet system is less than 22.000 t. For the stabilization of the phase near transition energy a system for the compensation of the oscillations of the length of the particle orbit is used in this project by means of which the critical energy is shifted to infinity. With this compensation process the enforced oscillations of particles, the energy of which is distinguished from the equilibrium momentum, are used. Every eighth magnet has an inversely directed magnetic field, and the order of this magnet is periodically changed. This compensation system makes it possible to attain rather high frequencies of the transversal oscillations of the particles, viz. 13,75 and 12,75 per revolution in the case of radial and vertical

Atomnaja Energija, 1, fasc.4, 31-33 (1956) CARD 2 / 2

PA - 1509

oscillations respectively. The maximum field strength in the orbit is from 10.000 to 12.000 Ørstedt and the length of the orbit is 1483 m. The main parameters of the orbit, the tolerances for the accuracy of the magnetic field, the data concerning the feeding of the magnetic system, and the most important data concerning the high frequency system are shown in tables. Among others the following values are given: Total number of magnets: 120, radius of the curvature of the principal magnet: 166,1 m; permitted deviation of momentum: 0,5%; permitted deviation of field strength: 0,25%; duration of the increase of the magnetic field: 3,8 sec, 6 cycles per minute; maximum strength of excitation current: 12 000 a; maximum voltage: 8 000 V; peak power: 96 000 kVA; frequency of the accelerating field at the beginning and at the end of the cycle of acceleration: 2,624 and 6,068 megacycle respectively. The magnets must consist of 5 parts weighing 38 t each, but they have one common winding. The total weight of the magnets together with constructional elements amounts to 22 000 tons. The peak power of 100 megawatts is generated by means of generators with flywheels. A linear accelerator for 100 MeV serves as injector. The proton absorbs ~ 100 keV per revolution.

Working out of results: The energies of the neutrons were measured by the method of flying-through time. The parameters of the levels were determined from the measured penetrability curves of samples of different thickness according to the "area" method. From the course of the experimental curve it is possible to determine the neutron width Γ_n by making use of the interference effect.

Results: Palladium: The levels at 13,25 and 32 eV were treated according to the method of the "surface of two samples". The resonance width determined from and averaged over the resonances 13 and 32 eV amounted to (220 ± 63) mV and was then used for the computation of the other levels. As palladium is an element with several isotopes, the unknown relative weights of the isotopes go into the results. Osmium: The radiation width Γ_γ for the levels at 10,3; 18,8 and 22 eV was determined. The average width of these levels is 67 mV and this value was used for the computation of the other levels. The data for all investigated resonances are shown in a table. The authors, moreover, observed levels at 109, 125, 144, 166 (weak), 208 and 333 eV. Indium: The authors were able to

PA - 1802

dissolve some levels that had hitherto been looked upon as units, into several levels. Also the results obtained in the case of the other elements mentioned are discussed in detail.

Conclusions: From the experimental material (concerning 100 resonances) which was gathered here there follows, among other things: 1.) Radiation widths do not change much from level to level and from isotope to isotope (palladium, iridium, osmium). Only in the case of uranium and tantalum is this change beyond the limits of experimental errors. The modification of radiation width in the case of uranium cannot be due to dependence on spin because the original nucleus is even-even. Also in the case of tantalum a noticeable change of radiation width (from level to level by about 1,5 times the amount) was noticed. This small difference in widths can be fully explained by the spin dependence of radiation width. The average values of the radiation widths of the elements investigated here are in agreement with theory. The neutron widths, even in the case of even-even nuclei change from level to level by the 10^2 -fold. The distribution of neutron widths cannot be described by means of an exponential curve. The values of Γ_n^0/\bar{D} change noticeably from element to element. Here \bar{D} denotes the average distance between levels.

PARTICLE ACCELERATOR: STRONG-FOCUSING ACCELERATORS

"Removal of the Beam from a Proton Accelerator with Strong Focusing at Energy of 7 Bev", by V.V. Vladimirovsky, L.L. Gol'din, Ye.N. Danil'tsev, D.G. Koshkarev, and N.N. Neyman, Pribory i Tekhnika Eksperimenta, No 3, November-December 1956, pp 31-35.

Examination of two methods of pulsed removal and one method of gradual removal of particles from the accelerator chamber. In the pulsed method of removal, the acquired additional impact is produced by the magnetic field of the current-carrying conductors. The removal is facilitated by the introduction of a separator, which is a magnetic channel with a large pulsed field. In the gradual removal of particles from the chamber, the natural oscillations of the particle are induced by means of parametric resonance.
